

Figure 8.1 Definition of Volume Coefficient Quantities

$$\bar{V}_h = x_h S_h / \bar{S} \quad (8.1)$$

$$\bar{V}_v = x_v S_v / S_b \quad (8.2)$$

Figure 8.1 defines the various quantities in Equations (8.1) and (8.2).

Tables 8.1 through 8.12 present the values of tail volume coefficients for twelve types of airplanes.

Having determined which type airplane best fits the airplane being designed, suitable values for \bar{V}_h and \bar{V}_v are selected. This can be done by averaging or by comparison to specific types. In deciding which value for \bar{V}_v to use, care must be taken that the lateral disposition of the engines is not too dissimilar. Note that vertical tail sizes are often dictated by the engine-out (i.e. V_{mc}) condition. Section 11.3 contains a vertical tail sizing procedure for V_{mc} .

Having selected the volume coefficients, and having determined the moment arms x_h and x_v from the fuselage arrangement sketches mentioned in Step 8.2, the tail areas can be computed from:

$$S_h = \bar{V}_h \bar{S} / x_h \quad (8.3)$$

$$S_v = \bar{V}_v S_b / x_v \quad (8.4)$$

The reader will have noted from the supersonic fighter configurations of Figures 3.25a and 3.27b that twin vertical tails are sometimes used. This is often done to avoid a very large single fin. The lateral placement of these twin verticals is a critical problem because of vortex shedding from the fuselage. These vortices can cause structural fatigue as well as a reduction in tail effectiveness.

b. Canard configurations.

The concept of volume coefficients can in principle be extended to a canard configuration. The problem is
